Dual High-Efficiency PWM Step-Down DC-DC Converter

General Description

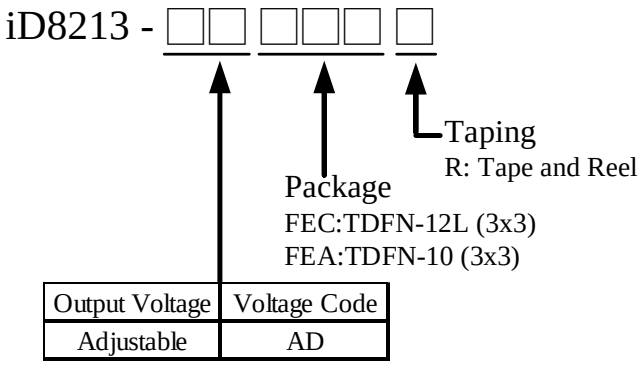
The iD8213 is a dual high efficiency Pulse Width Modulated (PWM) step-down DC-DC converter. It is capable of delivering 1.2A output current over a wide input voltage range from 2.6V to 5.5V, the iD8213 is ideally suited for portable electronic devices that are powered from 1-cell Li-ion battery or from other power sources within the range such as cellular phones, PDAs and other handheld devices.

Two operational modes are available: PWM/Low-Dropout auto-switch and shutdown modes. Internal synchronous rectifier with low $R_{DS(ON)}$ dramatically reduces conduction loss at PWM mode. No external Schottky diode is required in practical application.

The iD8213 enters Low-Dropout mode when normal PWM cannot provide regulated output voltage by continuously turning on the upper PMOS. The iD8213 enter shutdown mode and consumes less than 0.1μA when EN pin is pulled low.

The switching ripple is easily smoothed-out by small package filtering elements due to a fixed operation frequency of 1.5MHz. This along with small TDFN-12L and TDFN-10 package provides small PCB area application. Other features include soft start, lower internal reference voltage with 3% accuracy, over temperature protection, and over current protection.

Ordering Information



Output Voltage	Voltage Code
Adjustable	AD

Applications

- Mobile Phones
- Personal Information Appliances
- Wireless and DSL Modems
- MP3 Players
- Portable Instruments

Features

- 2.6V to 5.5V Input Range
- Adjustable Output Voltage
- 1.2A Output Current per Channel
- 95% Efficiency
- No Schottky Diode Required
- 40 μA Quiescent Current per Channel
- 1.5MHz Fixed-Frequency PWM Operation
- Small TDFN-12 and TDFN-10 Package
- RoHS Compliant and Green

Marking Information

For marking information, please contact our sales representative directly or through distributor around your location.

Absolute Maximum Ratings (Note 1)

Supply Voltage V_{IN}	6V
Power Dissipation, P_D @ T_A=25°C	
TDFN-12L / TDFN-10	2.083W
Thermal Resistance, θja	
TDFN-12L / TDFN-10	48°C/W
Lead Temperature	260°C
Storage Temperature	-65°C to 150°C
ESD Susceptibility	
HBM (Human Body Mode)	2kV
MM (Machine Mode)	200V

Recommended Operating Conditions

Input Voltage V_{IN}	2.6V to 5.5V
EN Input Voltage	0V to V_{IN}
Junction Temperature	-40°C to 125°C
Ambient Operating Temperature	-40°C to 85°C

Pin Description

Name	Description
VIN2	Power Input of Channel 2.
SW2	Pin for Switching of Channel 2.
GND	Ground. The exposed pad must be soldered to a large PCB and connected to GND for maximum power dissipation.
FB1	Feedback of Channel 1.
NC1, NC2	No Connection or Connect to V_{IN}.
EN1	Chip Enable of Channel 1 (Active High). $V_{EN1} \leqq V_{IN1}$.
VIN1	Power Input of Channel 1.
SW1	Pin for Switching of Channel 1.
FB2	Feedback of Channel 2.
EN2	Chip Enable of Channel 2 (Active High). $V_{EN2} \leqq V_{IN2}$.

Switching Frequency			1.5		MHz
NMOS Switch On Resistance	I_{SW}=200mA		200		mΩ
PMOS Switch On Resistance	I_{SW}=200mA		280		mΩ
PMOS Switch Current Limit		1.5			A
SW Leakage Current	V_{IN}=5.5V,V_{SW}=0 or 5.5V,EN= GND			10	μA
EN Input Current				1	μA
EN Input Low Voltage		0.4			V
EN Input High Voltage				1.5	V

Functional Description

The basic iD8213 application circuit is shown in Typical Application Circuit. External component selection is determined by the maximum load current and begins with the selection of the inductor value and operating frequency followed by C_{IN} and C_{OUT}.

Inductor Selection

For a given input and output voltage, the inductor value and operating frequency determine the ripple current. The ripple current ΔI_L increases with higher V_{IN} and decreases with higher inductance.

$$\Delta I_L = \left[\frac{V_{OUT}}{f \times L}\right] \times \left[1 - \frac{V_{OUT}}{V_{IN}}\right]$$

Having a lower ripple current reduces the ESR losses in the output capacitors and the output voltage ripple. Highest efficiency operation is achieved at low frequency with small ripple current. This, however, requires a large inductor.

A reasonable starting point for selecting the ripple current is ΔI_L = 0.4(I_{MAX}). The largest ripple current occurs at the highest V_{IN}. To guarantee that the ripple current stays below a specified maximum, the inductor value should be chosen according to the following equation:

$$L = \left[\frac{V_{OUT}}{f \times \Delta I_{L(MAX)}}\right] \times \left\{1 - \frac{V_{OUT}}{V_{IN(MAX)}}\right\}$$

Inductor Core Selection

Once the value for L is known, the type of inductor must be selected. High efficiency converters generally cannot afford the core loss found in low cost powdered iron cores, forcing the use of more expensive ferrite or permalloy cores. Actual core loss is independent of core size for a fixed inductor value but it is very dependent on the inductance selected. As the inductance increases, core losses decrease. However, increased inductance requires more turns of wire and therefore copper losses will increase.

Ferrite designs have very low core losses and are preferred at high switching frequencies, so design goals can concentrate on copper loss and preventing saturation. Ferrite core material saturates “hard”, which means that inductance collapses abruptly when the peak design current is exceeded.

This results in an abrupt increase in inductor ripple current and consequent output voltage ripple.

Do not allow the core to saturate!

Different core materials and shapes will change the size/current and price/current relationship of an inductor. Toroid or shielded pot cores in ferrite or permalloy materials are small and don't radiate energy but generally cost more than powdered iron core inductors with similar characteristics. The choice of which style inductor to use mainly depend on the price vs. size requirements and any radiated field/EMI requirements.

C_{IN} and C_{OUT} Selection

The input capacitance, C_{IN}, is needed to filter the trapezoidal current at the source of the top MOSFET. To prevent large ripple voltage, a low ESR input capacitor sized for the maximum RMS current should be used. RMS current is given by :

$$I_{RMS} = I_{OUT(MAX)} \frac{V_{OUT}}{V_{IN}} \sqrt{\frac{V_{IN}}{V_{OUT}} - 1}$$

This formula has a maximum at $V_{IN} = 2V_{OUT}$, where $I_{RMS} = I_{OUT}/2$. This simple worst-case condition is commonly used for design because even significant deviations do not offer much relief. Note that ripple current ratings from capacitor manufacturers are often based on only 2000 hours of life which makes it advisable to further de-rate the capacitor, or choose a capacitor rated at a higher temperature than required. Several capacitors may also be paralleled to meet size or height requirements in the design.

The selection of C_{OUT} is determined by the effective

series resistance (ESR) that is required to minimize voltage ripple and load step transients, as well as the amount of bulk capacitance that is necessary to ensure that the control loop is stable. Loop stability can be checked by viewing the load transient response as described in a later section.

The output ripple, ΔV_{OUT}, is determined by:

$$\Delta V_{OUT} \le \Delta I_L \left[ESR + \frac{1}{8 f C_{OUT}} \right]$$

The output ripple is highest at maximum input voltage since ΔI_L increases with input voltage. Multiple capacitors placed in parallel may be needed to meet the ESR and RMS current handling requirements. Dry tantalum, special polymer, aluminum electrolytic and ceramic capacitors are all available in surface mount packages. Special polymer capacitors offer very low ESR but have lower capacitance density than other types. Tantalum capacitors have the highest capacitance density but it is important to only use types that have been surge tested for use in switching power supplies. Aluminum electrolytic capacitors have significantly higher ESR but can be used in cost sensitive applications provided that consideration is given to ripple current ratings and long-term reliability. Ceramic capacitors have excellent low ESR characteristics but can have a high voltage coefficient and audible piezoelectric effects.

The high Q of ceramic capacitors with trace inductance can also lead to significant ringing.

Using Ceramic Input and Output Capacitors

Higher values, lower cost ceramic capacitors are now becoming available in smaller case sizes. Their high ripple current, high voltage rating and low ESR make them ideal for switching regulator applications. However, care must be taken when these capacitors are used at the input and output. When a ceramic capacitor is used at the input and the power is supplied by a wall adapter through long wires, a load step at the output can induce ringing at the input, V_{IN}. At best, this ringing can couple to the output and be mistaken as loop instability. At worst, a sudden inrush of current through the long wires can potentially cause a voltage spike at V_{IN} large enough to damage the part.

Output Voltage Programming

The resistive divider allows the FB pin to sense a fraction of the output voltage as shown in Figure 3.

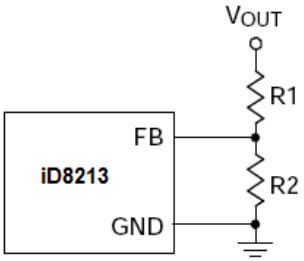

Figure 3. Setting the Output Voltage

For adjustable voltage mode, the output voltage is set by an external resistive divider according to the following equation :

$V_{OUT} = V_{REF} \times (1+ R1/R2)$

Where V_{REF} is the internal reference voltage (0.6V typical)

PSM Mode

As the output current drops, the iD8213 enters discontinuous conduction mode (DCM). If a very light load current only requires the switch on time to be less than $1/10F_{OSC}$ (minimum on time), the IC enters pulse-skipping mode. In this mode, the device prevents the switch from turning on for one or more switching cycles to prevent the output voltage from rising above the regulated voltage. According this, when iD8213 enters in PSM mode will get higher efficiency than PWM mode. Compared to normal PWM operation, the output ripple in pulse- skipping will be larger.

Efficiency Considerations

The efficiency of a switching regulator is equal to the output power divided by the input power times 100%. It

is often useful to analyze individual losses to determine what is limiting the efficiency and which change would produce the most improvement. Efficiency can be expressed as:

Efficiency = 100% – (L1+ L2+ L3+...)

where L1, L2, etc. are the individual losses as a percentage of input power. Although all dissipative elements in the circuit produce losses, two main sources usually account for most of the losses: V_{IN} quiescent current and I^2R losses.

The V_{IN} quiescent current loss dominates the efficiency loss at very low load currents whereas the I^2R loss dominates the efficiency loss at medium to high load currents. In a typical efficiency plot, the efficiency curve at very low load currents can be misleading since the actual power lost is of no consequence.

1.The V_{IN} quiescent current appears due to two components : the DC bias current and the gate charge currents. The gate charge current results from switching the gate capacitance of the internal power MOSFET switches. Each time the gate is switched from high to low to high again, a packet of charge ΔQ moves from V_{IN} to ground.

The resulting $\Delta Q/\Delta t$ is the current out of V_{IN} that is typically larger than the DC bias current. In continuous mode,

$I_{GATECHG} = f(Q_T + Q_B)$

where Q_T and Q_B are the gate charges of the internal top and bottom switches. Both the DC bias and gate charge losses are proportional to VIN and thus their effects will be more pronounced at higher supply voltages.

2. I^2R losses are calculated from the resistances of the internal switches, R_{SW} and external inductor R_L. In continuous mode the average output current flowing through inductor L is “chopped” between the main switch and the synchronous switch. Thus, the series resistance looking into the SW pin is a function of both top and bottom MOSFET $R_{DS(ON)}$ and the duty cycle (DC) is shown as follows :

$R_{SW} = R_{DS(ON)TOP} \times DC + R_{DS(ON)BOT} \times (1 - DC)$

The $R_{DS(ON)}$ for both the top and bottom MOSFETs can be obtained from the Typical Performance Characteristics curves. Thus, to obtain I^2R losses, simply add R_{SW} to R_L and multiply the result by the square of the average output current. Other losses including C_{IN} and C_{OUT} ESR dissipative losses and inductor core losses generally account for less than 2% of the total loss.

Thermal Considerations

The maximum power dissipation depends on the thermal resistance of IC package, PCB layout, the rate of surroundings airflow and temperature difference between junction to ambient. The maximum power dissipation can be calculated by following formula :

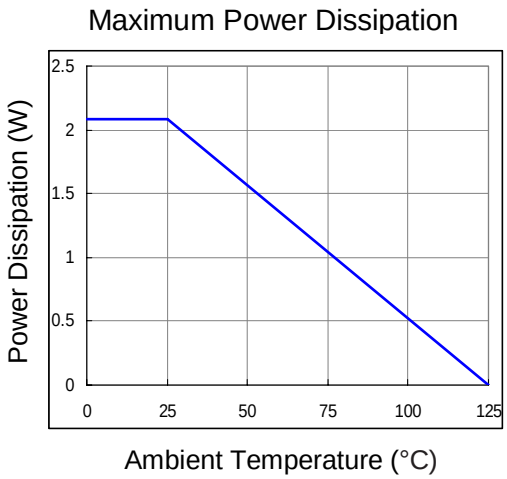
$P_{D(MAX)} = (T_{J(MAX)} - T_A) / \theta_{JA}$

Where $T_{J(MAX)}$ is the maximum junction temperature, T_A is the ambient temperature and the θ_{JA} is the junction to ambient thermal resistance. For recommended operating conditions specification of iD8213 DC/DC converter, where $T_{J(MAX)}$ is the maximum junction temperature of the die and T_A is the ambient temperature. The junction to ambient thermal resistance θ_{JA} is layout dependent. For TDFN-12L 3x3 packages, the thermal resistance θ_{JA} is 48°C/W on the standard JEDEC 51-7 four-layers thermal test board. The maximum power dissipation at T_A = 25°C can be calculated by following formula :

$P_{D(MAX)}$ = (125°C – 25°C) / (48°C/W) = 2.083W for TDFN-12L 3x3 packages

The maximum power dissipation depends on operating ambient temperature for fixed $T_{J(MAX)}$ and thermal resistance θ_{JA}. For iD8213 packages, the Figure 4 of derating curves allows the designer to see the effect of

rising ambient temperature on the maximum power allowed.



Checking Transient Response

The regulator loop response can be checked by looking at the load transient response. Switching regulators take several cycles to respond to a step in load current. When a load step occurs, V_{OUT} immediately shifts by an amount equal to ΔI_{LOAD} (ESR), where ESR is the effective series resistance of C_{OUT}. ΔI_{LOAD} also begins to charge or discharge C_{OUT} generating a feedback error signal used by the regulator to return V_{OUT} to its steady-state value. During this recovery time, V_{OUT} can be monitored for overshoot or ringing that would indicate a stability problem.

Table 1. Recommended Inductors

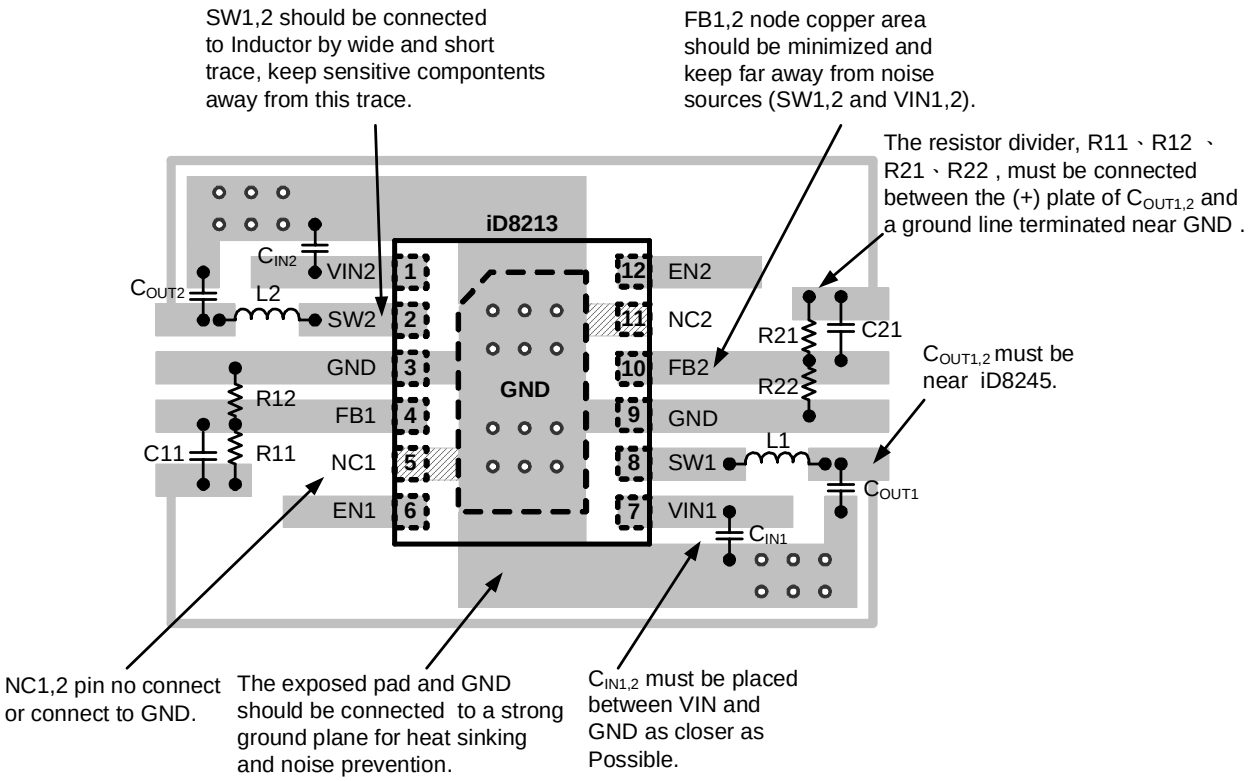
Layout Considerations

Follow the PCB layout guidelines for optimal performance of iD8213.

- For the main current paths, keep their traces short and wide.
- Put the input capacitor as close as possible to the device pins (VIN and GND).
- SW node is with high frequency voltage swing and should be kept small area. Keep analog components away from SW node to prevent stray capacitive noise pick-up.
- Connect feedback network behind the output capacitors. Keep the loop area small. Place the feedback components near the iD8213.
- Connect all analog grounds to a command node and then connect the command node to the power ground behind the output capacitors.



TDFN-12L Package

Layout Considerations

When laying out the printed circuit board, the following checklist should be used to ensure proper operation of the iD8213. These items are also illustrated graphically in layout diagram. Check the following in your layout:

1. The power traces, consisting of the GND trace, the SW trace and the IN trace should be kept short, direct and wide.

2. Does the FB pin connect directly to the V_{OUT}?

The R1 resistance must be connected between the (+) plate of C_{OUT1}.

The R3 resistance must be connected between the (+) plate of C_{OUT2}.

3. Does the (+) plate of C_{IN} connect to IN pin as closely as possible?

This capacitor avoided the AC current to the internal power MOSFETs.

4. Keep the switching node "SW" away from the sensitive FB node.

5. Keep the (–) plates of C_{IN1} and C_{OUT1} as close as possible.

6. Keep the (–) plates of C_{IN2} and C_{OUT2} as close as possible.
